

STAT 5361 Interim Report

A Simple and Effective Inequality Measure

Chamundeswari Koppiseti*

Shynggys Magzanov†

19 11 2020

Abstract

We will write later

1. Introduction

1.1. Measures of Inequality

There exist various types of metrics used by economists to measure the income inequality. The most widely exploited ones are the Lorenz curves and the Gini coefficient, each of which have their own advantages and limitations. Those obvious limitations include the requirement for the population mean and variance to exist, as well as down-weighting smaller incomes and that way stressing way more attention to the middle incomes. This paper analyzes another income inequality measure, namely using ratios of symmetric quantiles, that proves to be helpful to overcome previously mentioned disadvantages. In addition to that, it is proven that the given metric satisfies the median preserving principle and applicable to widely used income distributions. But the major benefit is that there is no need of parametric model assumption to work with the given inequality measure.

2. Importance of the Project

There are numerous reasons of why researchers and policymakers might be interested in getting a better picture of the economic inequality in the country. Research results in this field suggest that there is a strong relationship between income inequalities amid individuals and levels of poverty, mental illnesses, crime and social unrest. At the same time most of the public policies like welfare benefits, taxation, health care, etc. have direct influence on how the income is distributed. To properly plan how to address these issues one has to have a good measure of current income inequality. This is where the ratios of symmetric quantiles metric can be very useful to get more accurate result than it can be provided by the Gini coefficient or the Lorenz curves.

3. Preliminary content of the Project

1. Introduction

1.2. Concepts and Definitions

2. Examples with well-known income distributions

2.1. Inequality curves

2.2 Comparing I and G

3. Inference

3.1. Approximation of I

3.2 Confidence intervals

3.3 Resistance to outliers

4. Application

4.1. Disposable Personal Income

4.2. Gross Domestic Income

4.3. Earnings data of women

5. Conclusion

6. References

7. Appendix

4. Current Progress

Currently, the applicational part of the project on 3 real data sets was accomplished. The R-Script to calculate \hat{I} and \hat{G} was implemented and those metrics were computed for the data sets. Additionally, respective inequality curves were plotted.

4.1. Disposable Personal Income

The data of Disposable Personal Income can be obtained at <https://fred.stlouisfed.org/series/DSPI>.

```
DSPI <- read.csv("C:\\Users\\Asus\\Downloads\\DSPI.csv")
plot(DSPI, type = "l", main = "Disposable Personal Income")
```

```
QOR.ln <- function(u){
  # QOR function for the log-normal
  q.n.0 <- 1/dnorm(qnorm(u))
  q.n.1 <- qnorm(u)*q.n.0^2
  q.n.2 <- (1 + 2*qnorm(u)^2)*q.n.0^3
  1/(q.n.0^2 + 3*q.n.1 + q.n.2/q.n.0)
}

QOR.gld <- function(u, lambda = NULL){
  # QOR function for the GLD FKML parameterization
  if(is.null(lambda)) lambda <- fit.fkml(x)$lambda
}
```

```

13 <- lambda[3]
14 <- lambda[4]
(u^(13 - 1) + (1 - u)^(14 - 1))/(u^(13 - 3)*(13 - 2)*(13 - 1) +
(1 - u)^(14 - 3)*(14 - 2)*(14 - 1))
}

hatI <- function(x, J = 100, conf.level = 0.95,
bw.correct = TRUE, QOR.FUN = QOR.ln, ...){

n <- length(x)

us <- ((1:J) - 0.5)/J
Rs <- (xu2 <- quantile(x, us/2))/(x1u2 <- quantile(x, 1 - us/2))
I <- sum(1 - Rs)/J

if(!is.null(conf.level)){
v <- c(us/2, 1 - us/2)
qor <- QOR.FUN(v, ...)
bw <- 15^(1/5)*abs(qor)^(2/5)/n^(1/5)
if (bw.correct) bw[v <= bw] <- v[v <= bw]

kernepach <- function(u) 3/4*(1 - u^2)*(abs(u) <= 1)
m1 <- matrix(v, nrow = 2*J, ncol = n, byrow = FALSE)
m2 <- matrix(1:n, nrow = 2*J, ncol = n, byrow = TRUE)

consts <- kernepach((m1 - (m2 - 1)/n)*(1/bw))*(1/bw) -

R_p <- function(x, J = 100){
  us <- ((1:J) - 0.5)/J
  Rs <- (quantile(x, us/2))/(quantile(x, 1 - us/2))
  return(cbind(us, Rs))
}

ineq_DSPI <- R_p(DSPI)
plot(ineq_DSPI, type = "l", main = "DSPI Inequality curve",
     xlab = "p", ylab = "R(p)")
```

Firstly, I and G were calculated for the Disposable Personal Income Data. It appears that $\hat{I} = 0.7561$, which is an estimate of I , with a standard error of 0.0106. Additionally, 95% confidence interval of \hat{I} was calculated to be (0.7352, 0.7769). While $\hat{G} = 0.4872$ is significantly lower, with a standard error of 0.0095 and respective 95% confidence interval of (0.4686, 0.5059).

4.2. Gross Domestic Income

The data on Gross Domestic Income can be found here: <https://fred.stlouisfed.org/series/GDI>.

```
GDI <- read.csv("C:\\Users\\Asus\\Downloads\\GDI.csv")  
plot(GDI, type = "l", main = "Gross Domestic Income")
```

```
GDI <- GDI$GDI  
I_gdi <- hatI(GDI)  
I_gdi
```

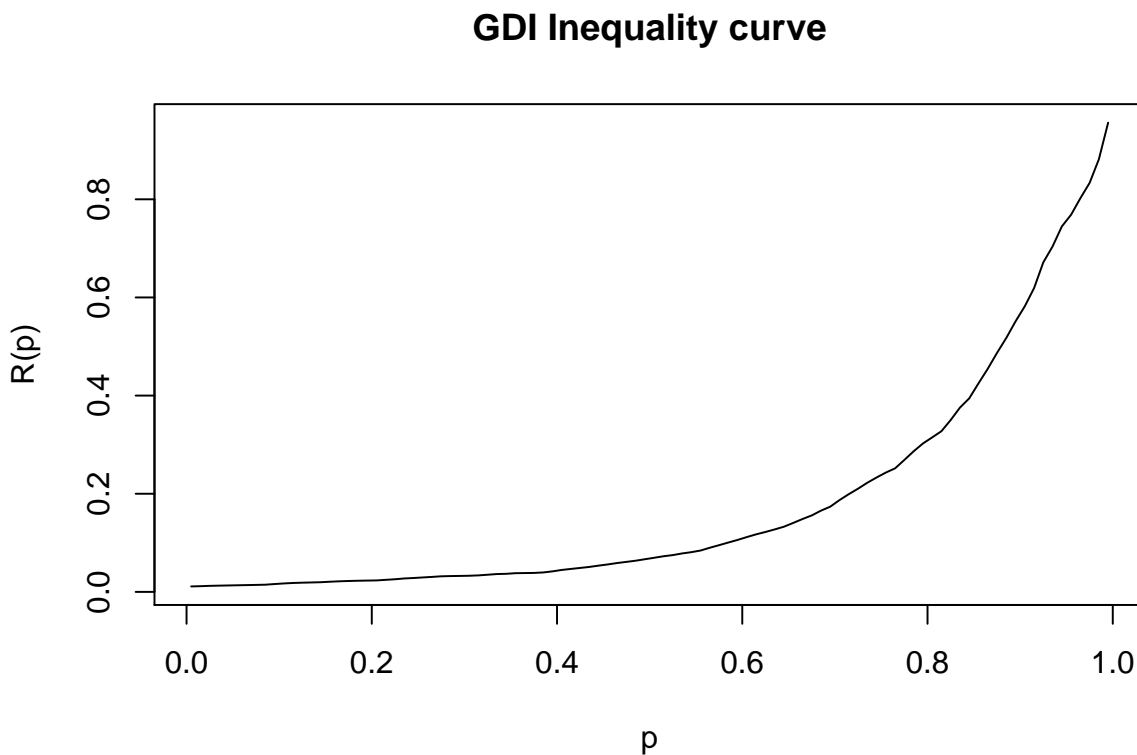

```
## $I  
## [1] 0.8204182  
##  
## $SE  
## [1] 0.01624378  
##  
## $conf.int  
## [1] 0.7885809 0.8522554
```

```
G_gdi <- hatG(GDI)  
G_gdi
```

```
## $G  
## [1] 0.549877
```

```
##
## $SE
## [1] 0.01613956
##
## $conf.int
## [1] 0.5182440 0.5815099

ineq_GDI <- R_p(GDI)
plot(ineq_GDI, type = "l", main = "GDI Inequality curve",
      xlab = "p", ylab = "R(p)")
```

As a result, ratio of symmetric quantiles of the GDI is $\hat{I} = 0.8204$ with a standard error 0.0162 and confidence interval (0.7886, 0.8523). At the same time $\hat{G} = 0.5499$ with a standard error of 0.0161 and CI (0.5182, 0.5815).

4.3. Earnings data of women

The data on Earnings of women in the US between 1979 and 2020 can be obtained from: <https://fred.stlouisfed.org/series/LES1252882700Q>.

```
LES <- read.csv("C:\\Users\\Asus\\Downloads\\LES.csv")
plot(LES, type = "l", main = "Median usual weekly nominal earnings for women")
```

Median usual weekly nominal earnings for women

```
LES <- LES$LES
I_les <- hatI(LES)
I_les
```

```
## $I
## [1] 0.4665993
##
## $SE
## [1] 0.01831842
##
## $conf.int
## [1] 0.4306959 0.5025028
```

```
G_les <- hatG(LES)
G_les
```

```
## $G
## [1] 0.2199384
##
## $SE
## [1] 0.009415175
##
## $conf.int
## [1] 0.2014850 0.2383918
```

```
ineq_LES <- R_p(LES)
plot(ineq_LES, type = "l", main = "Earnings of women Inequality curve",
     xlab = "p", ylab = "R(p)")
```

Results reveal that $\hat{I} = 0.4666$ with a standard error 0.0183 and CI (0.4307, 0.5025). While Gini coefficient is $\hat{G} = 0.2199 \pm 0.0094$ with CI (0.2015, 0.2384).

5. Prospective plans

To complete the project we need to elaborate on providing interpretation of obtained results. Additionally, we need to implement an algorithm to plot inequality curves using the well-known income distributions and compare values of I and G for them. Lastly, we need to include all the theoretical background of the concepts that were discussed in this project.
